Not illustrated. 1902 Excerpt: . transformers must regulate closely, and hence have a high all-day core loss, for there are no means of regulating the one independently of the others. The best results are obtained by using large transformers, or a bank of transformers fed direct from the station and regulated therefrom, the consumers drawing supply from the low-pressure secondary network. In working transformers for arc lamp and motor supply, the selfinduction of these apparatus reduces the load-factor; that is to say, the amperes required are more than what the real power calls for. The volts and amperes do not reach the maximum value at the same instant, hence the amperes rise in value in an inductive circuit. Types of Transformers The load-factor is the real power divided by the apparent power. A motor may be taking 200 volts and 20 amperes, apparently 4000 watts; but if we measured the power actually by an alternating current dynamo meter, we might find it only 3200 watts, and $4000 = \text{anc a would he the powerfactor}$. In determining the size of transformers to be used, the power-factor of the circuit must be taken into consideration. The power consumed in a circuit divided by the power-factor will give the capacity required in transformers. For example, if a 4-h.p. motor has a full-load power-factor of .8, a transformer having a capacity of = 5000 watts will be required. This point should not be overlooked when transformers have to supply an inductive load. Incandescent lamps are, of...
